(54) Title: ENVIRONMENTAL SYSTEM INCLUDING VACUUM SCAVENGE FOR AN IMMERSION LITHOGRAPHY APPARATUS

(57) Abstract: An environmental system (26) for controlling an environment in a gap (246) between an optical assembly (16) and a device (30) includes a fluid barrier (254) and an immersion fluid system (252). The fluid barrier (254) is positioned near the device (30). The immersion fluid system (252) delivers an immersion fluid (248) that fills the gap (246). The immersion fluid system (252) collects the immersion fluid (248) that is directly between the fluid barrier (254) and the device (30). The fluid barrier (254) can include a scavenge inlet (286) that is positioned near the device (30), and the immersion fluid system (252) can include a low pressure source (392A) that is in fluid communication with the scavenge inlet (286). The fluid barrier (254) confines any vapor (249) of the immersion fluid (248) and prevents it from perturbing a measurement system (22). Additionally, the environmental system (26) can include a bearing fluid source (290B) that directs a bearing fluid (290C) between the fluid barrier (254) and the device (30) to support the fluid barrier (254) relative to the device (30).

For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.

5 UNITED STATES PATENT APPLICATION
of
ANDREW J. HAZELTON AND MICHAEL SOGARD
for
ENVIRONMENTAL SYSTEM INCLUDING VACUUM SCAVANGE FOR AN
10 IMMERSION LITHOGRAPHY APPARATUS

RELATED APPLICATION

15 This application claims priority on Provisional Application Serial No. 60/462,112 filed on April 10, 2003 and entitled "VACUUM RING SYSTEM AND WICK RING SYSTEM FOR IMMERSION LITHOGRAPHY METHOD AND DEVICE FOR CONTROLLING THERMAL DISTORTION IN ELEMENTS OF A LITHOGRAPHY STSTEM" and Provisional Application Serial No. 60/484,476 filed on July 1, 2003 and entitled "FLUID CONTROL SYSTEM FOR IMMERSION
20 LITHOGRAPHY TOOL". As far as is permitted, the contents of provisional Application Serial Nos. 60/462,112 and 60/484,476 are incorporated herein by reference.

BACKGROUND

25 Lithography exposure apparatuses are commonly used to transfer images from a reticle onto a semiconductor wafer during semiconductor processing. A typical exposure apparatus includes an illumination source, a reticle stage assembly that positions a reticle, an optical assembly, a wafer stage assembly
30 that positions a semiconductor wafer, and a measurement system that precisely monitors the position of the reticle and the wafer.

Immersion lithography systems utilize a layer of immersion fluid that completely fills a gap between the optical assembly and the wafer. The wafer is moved rapidly in a typical lithography system and it would be expected to carry

the immersion fluid away from the gap. This immersion fluid that escapes from the gap can interfere with the operation of other components of the lithography system. For example, the immersion fluid and its vapor can interfere with the measurement system that monitors the position of the wafer.

5

SUMMARY

The present invention is directed to an environmental system for controlling an environment in a gap between an optical assembly and a device that is retained by a device stage. The environmental system includes a fluid barrier and an immersion fluid system. The fluid barrier is positioned near the device and encircles the gap. The immersion fluid system delivers an immersion fluid that fills the gap.

In one embodiment, the immersion fluid system collects the immersion fluid that is directly between the fluid barrier and at least one of the device and the device stage. In this embodiment, the fluid barrier includes a scavenge inlet that is positioned near the device, and the immersion fluid system includes a low pressure source that is in fluid communication with the scavenge inlet. Additionally, the fluid barrier can confine and contain the immersion fluid and any of the vapor from the immersion fluid in the area near the gap.

In another embodiment, the environmental system includes a bearing fluid source that directs a bearing fluid between the fluid barrier and the device to support the fluid barrier relative to the device. In this embodiment, the fluid barrier includes a bearing outlet that is positioned near the device. Further, the bearing outlet is in fluid communication with the bearing fluid source.

Additionally, the environmental system can include a pressure equalizer that allows the pressure in the gap to be approximately equal to the pressure outside the fluid barrier. In one embodiment, for example, the pressure equalizer is a channel that extends through the fluid barrier.

Moreover, the device stage can include a stage surface that is in approximately the same plane as a device exposed surface of the device. As an example, the device stage can include a device holder that retains the device, a guard that defines the stage surface, and a mover assembly that moves one of the device holder and the guard so that the device exposed surface is

approximately in the same plane as the stage surface. In one embodiment, the mover assembly moves the guard relative to the device and the device holder. In another embodiment, the mover assembly moves the device holder and the device relative to the guard.

5 The present invention is also directed to an exposure apparatus, a wafer, a device, a method for controlling an environment in a gap, a method for making an exposure apparatus, a method for making a device, and a method for manufacturing a wafer.

DESCRIPTION

10 Figure 1 is a schematic illustration of a precision assembly, namely an exposure apparatus 10 having features of the present invention. The exposure apparatus 10 includes an apparatus frame 12, an illumination system 14 (irradiation apparatus), an optical assembly 16, a reticle stage assembly 18, a device stage assembly 20, a measurement system 22, a control system 24, and a
15 fluid environmental system 26. The design of the components of the exposure apparatus 10 can be varied to suit the design requirements of the exposure apparatus 10.

A number of Figures include an orientation system that illustrates an X axis, a Y axis that is orthogonal to the X axis, and a Z axis that is orthogonal to the X
20 and Y axes. It should be noted that these axes can also be referred to as the first, second and third axes.

The exposure apparatus 10 is particularly useful as a lithographic device that transfers a pattern (not shown) of an integrated circuit from a reticle 28 onto a semiconductor wafer 30 (illustrated in phantom). The wafer 30 is also referred to
25 generally as a device or work piece. The exposure apparatus 10 mounts to a mounting base 32, e.g., the ground, a base, or floor or some other supporting structure.

There are a number of different types of lithographic devices. For example, the exposure apparatus 10 can be used as a scanning type photolithography
30 system that exposes the pattern from the reticle 28 onto the wafer 30 with the reticle 28 and the wafer 30 moving synchronously. In a scanning type lithographic device, the reticle 28 is moved perpendicularly to an optical axis of the optical assembly 16 by the reticle stage assembly 18 and the wafer 30 is moved perpendicularly to the optical axis of the optical assembly 16 by the wafer stage

assembly 20. Scanning of the reticle 28 and the wafer 30 occurs while the reticle 28 and the wafer 30 are moving synchronously.

Alternatively, the exposure apparatus 10 can be a step-and-repeat type photolithography system that exposes the reticle 28 while the reticle 28 and the wafer 30 are stationary. In the step and repeat process, the wafer 30 is in a constant position relative to the reticle 28 and the optical assembly 16 during the exposure of an individual field. Subsequently, between consecutive exposure steps, the wafer 30 is consecutively moved with the wafer stage assembly 20 perpendicularly to the optical axis of the optical assembly 16 so that the next field of the wafer 30 is brought into position relative to the optical assembly 16 and the reticle 28 for exposure. Following this process, the images on the reticle 28 are sequentially exposed onto the fields of the wafer 30, and then the next field of the wafer 30 is brought into position relative to the optical assembly 16 and the reticle 28.

However, the use of the exposure apparatus 10 provided herein is not limited to a photolithography system for semiconductor manufacturing. The exposure apparatus 10, for example, can be used as an LCD photolithography system that exposes a liquid crystal display device pattern onto a rectangular glass plate or a photolithography system for manufacturing a thin film magnetic head.

The apparatus frame 12 supports the components of the exposure apparatus 10. The apparatus frame 12 illustrated in Figure 1 supports the reticle stage assembly 18, the wafer stage assembly 20, the optical assembly 16 and the illumination system 14 above the mounting base 32.

The illumination system 14 includes an illumination source 34 and an illumination optical assembly 36. The illumination source 34 emits a beam (irradiation) of light energy. The illumination optical assembly 36 guides the beam of light energy from the illumination source 34 to the optical assembly 16. The beam illuminates selectively different portions of the reticle 28 and exposes the wafer 30. In Figure 1, the illumination source 34 is illustrated as being supported above the reticle stage assembly 18. Typically, however, the illumination source 34 is secured to one of the sides of the apparatus frame 12 and the energy beam from the illumination source 34 is directed to above the reticle stage assembly 18 with the illumination optical assembly 36.

The illumination source 34 can be a light source such as a mercury g-line source (436 nm) or i-line source (365 nm), a KrF excimer laser (248 nm), an ArF excimer laser (193 nm) or a F₂ laser (157 nm). The optical assembly 16 projects and/or focuses the light passing through the reticle 28 to the wafer 30. Depending upon the design of the exposure apparatus 10, the optical assembly 16 can magnify or reduce the image illuminated on the reticle 28. It could also be a 1x magnification system.

When far ultra-violet radiation such as from the excimer laser is used, glass materials such as quartz and fluorite that transmit far ultra-violet rays can be used in the optical assembly 16. The optical assembly 16 can be either catadioptric or refractive.

Also, with an exposure device that employs radiation of wavelength 200 nm or lower, use of the catadioptric type optical system can be considered. Examples of the catadioptric type of optical system include the disclosure Japan Patent Application Disclosure No.8-171054 published in the Official Gazette for Laid-Open Patent Applications and its counterpart U.S. Patent No, 5,668,672, as well as Japan Patent Application Disclosure No.10-20195 and its counterpart U.S. Patent No. 5,835,275. In these cases, the reflecting optical device can be a catadioptric optical system incorporating a beam splitter and concave mirror. Japan Patent Application Disclosure No.8-334695 published in the Official Gazette for Laid-Open Patent Applications and its counterpart U.S. Patent No. 5,689,377 as well as Japan Patent Application Disclosure No.10-3039 and its counterpart U.S. Patent Application No. 873,605 (Application Date: 6-12-97) also use a reflecting-refracting type of optical system incorporating a concave mirror, etc., but without a beam splitter, and can also be employed with this invention. As far as is permitted, the disclosures in the above-mentioned U.S. patents, as well as the Japan patent applications published in the Official Gazette for Laid-Open Patent Applications are incorporated herein by reference.

In one embodiment, the optical assembly 16 is secured to the apparatus frame 12 with one or more optical mount isolators 37. The optical mount isolators 37 inhibit vibration of the apparatus frame 12 from causing vibration to the optical assembly 16. Each optical mount isolator 37 can include a pneumatic cylinder (not shown) that isolates vibration and an actuator (not shown) that isolates vibration and controls the position with at least two degrees of motion. Suitable

optical mount isolators 37 are sold by Integrated Dynamics Engineering, located in Woburn, MA. For ease of illustration, two spaced apart optical mount isolators 37 are shown as being used to secure the optical assembly 16 to the apparatus frame 12. However, for example, three spaced apart optical mount isolators 37
5 can be used to kinematically secure the optical assembly 16 to the apparatus frame 12.

The reticle stage assembly 18 holds and positions the reticle 28 relative to the optical assembly 16 and the wafer 30. In one embodiment, the reticle stage assembly 18 includes a reticle stage 38 that retains the reticle 28 and a reticle
10 stage mover assembly 40 that moves and positions the reticle stage 38 and reticle 28.

Somewhat similarly, the device stage assembly 20 holds and positions the wafer 30 with respect to the projected image of the illuminated portions of the reticle 28. In one embodiment, the device stage assembly 20 includes a device
15 stage 42 that retains the wafer 30, a device stage base 43 that supports and guides the device stage 42, and a device stage mover assembly 44 that moves and positions the device stage 42 and the wafer 28 relative to the optical assembly 16 and the device stage base 43. The device stage 42 is described in more detail below.

Each stage mover assembly 40, 44 can move the respective stage 38, 42 with three degrees of freedom, less than three degrees of freedom, or more than three degrees of freedom. For example, in alternative embodiments, each stage mover assembly 40, 44 can move the respective stage 38, 42 with one, two, three, four, five or six degrees of freedom. The reticle stage mover assembly 40
20 and the device stage mover assembly 44 can each include one or more movers, such as rotary motors, voice coil motors, linear motors utilizing a Lorentz force to generate drive force, electromagnetic movers, planar motors, or some other force movers.

Alternatively, one of the stages could be driven by a planar motor, which
30 drives the stage by an electromagnetic force generated by a magnet unit having two-dimensionally arranged magnets and an armature coil unit having two-dimensionally arranged coils in facing positions. With this type of driving system, either the magnet unit or the armature coil unit is connected to the stage base and the other unit is mounted on the moving plane side of the stage.

Movement of the stages as described above generates reaction forces that can affect performance of the photolithography system. Reaction forces generated by the wafer (substrate) stage motion can be mechanically transferred to the floor (ground) by use of a frame member as described in US Patent No. 5,528,100 and published Japanese Patent Application Disclosure No. 8-136475. Additionally, reaction forces generated by the reticle (mask) stage motion can be mechanically transferred to the floor (ground) by use of a frame member as described in US Patent No. 5,874,820 and published Japanese Patent Application Disclosure No. 8-330224. As far as is permitted, the disclosures in US Patent Numbers 5,528,100 and 5,874,820 and Japanese Patent Application Disclosure No. 8-330224 are incorporated herein by reference.

The measurement system 22 monitors movement of the reticle 28 and the wafer 30 relative to the optical assembly 16 or some other reference. With this information, the control system 24 can control the reticle stage assembly 18 to precisely position the reticle 28 and the device stage assembly 20 to precisely position the wafer 30. The design of the measurement system 22 can vary. For example, the measurement system 22 can utilize multiple laser interferometers, encoders, mirrors, and/or other measuring device. The stability of the measurement system 22 is essential for accurate transfer of an image from the reticle 28 to the wafer 30.

The control system 24 receives information from the measurement system 22 and controls the stage mover assemblies 18, 20 to precisely position the reticle 28 and the wafer 30. Additionally, the control system 24 can control the operation of the environmental system 26. The control system 24 can include one or more processors and circuits.

The environmental system 26 controls the environment in a gap 246 (illustrated in Figure 2B) between the optical assembly 16 and the wafer 30. The gap 246 includes an imaging field 250 (illustrated in Figure 2A). The imaging field 250 includes the area adjacent to the region of the wafer 30 that is being exposed and the area in which the beam of light energy travels between the optical assembly 16 and the wafer 30. With this design, the environment system 26 can control the environment in the exposure area 250.

The desired environment created and/or controlled in the gap 246 by the environmental system 26 can vary accordingly to the wafer 30 and the design of

the rest of the components of the exposure apparatus 10, including the illumination system 14. For example, the desired controlled environment can be a fluid such as water. The environmental system 26 is described in more detail below.

5 A photolithography system (an exposure apparatus) according to the embodiments described herein can be built by assembling various subsystems, including each element listed in the appended claims, in such a manner that prescribed mechanical accuracy, electrical accuracy, and optical accuracy are maintained. In order to maintain the various accuracies, prior to and following
10 assembly, every optical system is adjusted to achieve its optical accuracy. Similarly, every mechanical system and every electrical system are adjusted to achieve their respective mechanical and electrical accuracies. The process of assembling each subsystem into a photolithography system includes mechanical interfaces, electrical circuit wiring connections and air pressure plumbing
15 connections between each subsystem. Needless to say, there is also a process where each subsystem is assembled prior to assembling a photolithography system from the various subsystems. Once a photolithography system is assembled using the various subsystems, a total adjustment is performed to make sure that accuracy is maintained in the complete photolithography system.
20 Additionally, it is desirable to manufacture an exposure system in a clean room where the temperature and cleanliness are controlled.

Figure 2A is a cut-away view taken on line 2A-2A in Figure 1 that illustrates a portion of the exposure apparatus 10 including the optical assembly 16, the device stage 42, the environmental system 26, and the wafer 30. The imaging
25 field 250 (illustrated in phantom) is also illustrated in Figure 2A.

In one embodiment, the environmental system 26 fills the imaging field 250 and the rest of the gap 246 (illustrated in Figure 2B) with an immersion fluid 248 (illustrated in Figure 2B). As used herein, the term "fluid" shall mean and include a liquid and/or a gas, including any fluid vapor.

30 The design of the environmental system 26 and the components of the environmental system 26 can be varied. In the embodiment illustrated in Figure 2A, the environmental system 26 includes an immersion fluid system 252 and a fluid barrier 254. In this embodiment, (i) the immersion fluid system 252 delivers and/or injects the immersion fluid 248 into the gap 246 and captures the

immersion fluid 248 flowing from the gap 246, and (ii) the fluid barrier 254 inhibits the flow of the immersion fluid 248 away from near the gap 246.

The design of the immersion fluid system 252 can vary. For example, the immersion fluid system 252 can inject the immersion fluid 248 at one or more locations at or near the gap 246 and/or the edge of the optical assembly 16. Alternatively, the immersion fluid 248 may be injected directly between the optical assembly 16 and the wafer 30. Further, the immersion fluid system 252 can scavenge the immersion fluid 248 at one or more locations at or near the gap 246 and/or the edge of the optical assembly 16. In the embodiment illustrated in Figure 2A, the immersion fluid system 252 includes four, spaced apart injector/scavenge pads 258 (illustrated in phantom) positioned near the perimeter of the optical assembly 16 and an injector/scavenge source 260. These components are described in more detail below.

Figure 2A also illustrates that the optical assembly 16 includes an optical housing 262A, a last optical element 262B, and an element retainer 262C that secures the last optical element 262B to the optical housing 262A.

Figure 2B is a cut-away view of the portion of the exposure apparatus 10 of Figure 2A, including (i) the optical assembly 16 with the optical housing 262A, the optical element 262B, and the element retainer 262C, (ii) the device stage 42, and (iii) the environmental system 26. Figure 2B also illustrates the gap 246 between the last optical element 262B and the wafer 30, and that the immersion fluid 248 (illustrated as circles) fills the gap 246. In one embodiment, the gap 246 is approximately 1mm.

In one embodiment, the fluid barrier 254 contains the immersion fluid 248, including any fluid vapor 249 (illustrated as triangles) in the area near the gap 246 and forms and defines an interior chamber 263 around the gap 246. In the embodiment illustrated in Figure 2B, the fluid barrier 254 includes a containment frame 264 (also referred to herein as a surrounding member), a seal 266, and a frame support 268. The interior chamber 263 represents the enclosed volume defined by the containment frame 264, the seal 266, the optical housing 262A and the wafer 30. The fluid barrier 254 restricts the flow of the immersion fluid 248 from the gap 246, assists in maintaining the gap 246 full of the immersion fluid 248, allows for the recovery of the immersion fluid 248 that escapes from the gap 246, and contains any vapor 249 from the fluid. In one embodiment, the fluid

barrier 254 encircles and runs entirely around the gap 246. Further, in one embodiment, the fluid barrier 254 confines the immersion fluid 248 and its vapor 249 to a region on the wafer 30 and the device stage 42 centered on the optical assembly 16.

5 Containment of both the immersion fluid 248 and its vapor 249 can be important for the stability of the lithography tool. For example, stage measurement interferometers are sensitive to the index of refraction of the ambient atmosphere. For the case of air with some water vapor present at room temperature and 633 nm laser light for the interferometer beam, a change of 1%
10 in relative humidity causes a change in refractive index of approximately 10^{-8} . For a 1 m total beam path this can represent an error of 10 nm in stage position. If the immersion fluid 248 is water, a droplet of water 7 mm in diameter evaporating into a 1 m^3 volume changes the relative humidity by 1%. Relative humidity is typically monitored and corrected for by the control system 24, but this is based on the
15 assumption that the relative humidity is uniform, so that its value is the same in the interferometer beams as at the monitoring point. However, if droplets of water and its attendant vapor are scattered around on the wafer and stage surfaces, the assumption of uniform relative humidity may not be valid.

 In addition to the risk to the interferometer beams, water evaporation may
20 also create temperature control problems. The heat of vaporization of water is about 44 kJ/mole. Evaporation of the 7 mm drop mentioned above will absorb about 430 J which must be supplied by the adjacent surfaces.

 Figure 2C illustrates a perspective view of one embodiment of the containment frame 264. In this embodiment, the containment frame 264 is
25 annular ring shaped and encircles the gap 246 (illustrated in Figure 2B). Additionally, in this embodiment, the containment frame 264 includes a top side 270A, an opposed bottom side 270B (also referred to as a first surface) that faces the wafer 30, an inner side 270C that faces the gap 246, and an outer side 270D. It should be noted that the terms top and bottom are used merely for convenience
30 and the orientation of the containment frame 264 can be rotated. It should also be noted that the containment frame 264 can have another shape. Alternatively, for example, the containment frame 264 can be rectangular frame shaped or octagonal frame shaped.

Additionally, as provided herein, the containment frame 254 may be temperature controlled to stabilize the temperature of the immersion fluid 248.

Referring back to Figure 2B, the seal 266 seals the containment frame 264 to the optical assembly 16 and allows for some motion of the containment frame 264 relative to the optical assembly 16. In one embodiment, the seal 266 is made of a flexible, resilient material that is not influenced by the immersion fluid 248. Suitable materials for the seal 266 include rubber, Buna-N, neoprene, Viton or plastic. Alternatively the seal 266 may be a bellows made of a metal such as stainless steel or rubber or a plastic.

Figure 2D illustrates an enlarged view of a portion of Figure 2B, in partial cut-away. The frame support 268 connects and supports the containment frame 264 to the apparatus frame 12 and the optical assembly 16 above the wafer 30 and the device stage 42. In one embodiment, the frame support 268 supports all of the weight of the containment frame 264. Alternatively, for example, the frame support 268 can support only a portion of the weight of the containment frame 264. In one embodiment, the frame support 268 can include one or more support assemblies 274. For example, the frame support 268 can include three spaced apart support assemblies 274 (only two are illustrated). In this embodiment, each support assembly 274 extends between the apparatus frame 12 and the top side 270A of the containment frame 264.

In one embodiment, each support assembly 274 is a flexure. As used herein, the term "flexure" shall mean a part that has relatively high stiffness in some directions and relatively low stiffness in other directions. In one embodiment, the flexures cooperate (i) to be relatively stiff along the X axis and along the Y axis, and (ii) to be relatively flexible along the Z axis. The ratio of relatively stiff to relatively flexible is at least approximately 100/1, and can be at least approximately 1000/1. Stated another way, the flexures can allow for motion of the containment frame 264 along the Z axis and inhibit motion of the containment frame 264 along the X axis and the Y axis. In this embodiment, the support assembly 274 passively supports the containment frame 264.

Alternatively, for example, each support assembly 274 can be an actuator that can be used to adjust the position of the containment frame 264 relative to the wafer 30 and the device stage 42. Additionally, the frame support 268 can include a frame measurement system 275 that monitors the position of the containment

frame 264. For example, the frame measurement system 275 can monitor the position of the containment frame 264 along the Z axis, about the X axis, and/or about the Y axis. With this information, the support assemblies 274 can be used to adjust the position of the containment frame 264. In this embodiment, the support assembly 274 can actively adjust the position of the containment frame 264.

In one embodiment, the environmental system 26 includes one or more pressure equalizers 276 that can be used to control the pressure in the chamber 263. Stated another way, the pressure equalizers 276 inhibit atmospheric pressure changes or pressure changes associated with the fluid control from creating forces between the containment frame 264 and the wafer 30 or the last optical element 262B. For example, the pressure equalizers 276 can cause the pressure on the inside of the chamber 263 and/or in the gap 246 to be approximately equal to the pressure on the outside of the chamber 263. For example, each pressure equalizer 276 can be a channel that extends through the containment frame 264. In one embodiment, a tube 277 (only one is illustrated) is attached to the channel of each pressure equalizer 276 to convey any fluid vapor away from the measurement system 22 (illustrated in Figure 1). In alternative embodiments, the pressure equalizer 276 allow for a pressure difference of less than approximately 0.01, 0.05, 0.1, 0.5, or 1.0 PSI.

Figure 2B also illustrates several injector/scavenge pads 258. Figure 2D illustrates one injector/scavenge pad 258 in more detail. In this embodiment, each of the injector/scavenge pads 258 includes a pad outlet 278A and a pad inlet 278B that are in fluid communication with the injector/scavenge source 260. At the appropriate time, the injector/scavenge source 260 provides immersion fluid 248 to the pad outlet 278A that is released into the chamber 263 and draws immersion fluid 248 through the pad inlets 278B from the chamber 263.

Figures 2B and 2D also illustrate that the immersion fluid 248 in the chamber 263 sits on top of the wafer 30. As the wafer 30 moves under the optical assembly 16, it will drag the immersion fluid 248 in the vicinity of a top, device surface 279 of the wafer 30 with the wafer 30 into the gap 246.

In one embodiment, referring to Figures 2B and 2D, the device stage 42 includes a stage surface 280 that has approximately the same height along the Z axis as the top, device exposed surface 279 of the wafer 30. Stated another way,

in one embodiment, the stage surface 280 is in approximately the same plane as the device exposed surface 279. In alternative embodiments, for example, approximately the same plane shall mean that the planes are within approximately 1, 10, 100 or 500 microns. As a result thereof, the distance between the bottom side 270B of the containment frame 264 and the wafer 30 is approximately equal to the distance between the bottom side 270B of the containment frame 264 and the device stage 42. In one embodiment, for example, the device stage 42 can include a disk shaped recess 282 for receiving the wafer 30. Alternative designs of the device stage 42 are discussed below.

Figure 2D illustrates that a frame gap 284 exists between the bottom side 270B of the containment frame 264 and the wafer 30 and/or the device stage 42 to allow for ease of movement of the device stage 42 and the wafer 30 relative to the containment frame 264. The size of the frame gap 284 can vary. For example, the frame gap 284 can be between approximately 5 μ m and 3 mm. In alternative examples, the frame gap 284 can be approximately 5, 10, 50, 100, 150, 200, 250, 300, 400, or 500 microns.

In certain embodiments, the distance between the bottom side 270B and at least one of the wafer 30 and/or the device stage 42 is shorter than a distance between the end surface (e.g. the last optical element 262B or the bottom of the optical housing 262A) of the optical assembly 16 and at least one of the wafer 30 and/or the device stage 42.

Additionally, a wafer gap 285 can exist between the edge of the wafer 30 and the wafer stage 42. In one embodiment, the wafer gap 285 is as narrow as possible to minimize leakage when the wafer 30 is off-center from the optical assembly 16 and lying partly within and partly outside the fluid containment frame 264 region. For example, in alternative embodiments, the wafer gap 285 can be approximately 1, 10, 50, 100, 500, or 1000 microns.

Figure 2D also illustrates that some of the immersion fluid 248 flows between the containment frame 264 and the wafer 30 and/or the device stage 42. In one embodiment, the containment frame 264 includes one or more scavenge inlets 286 that are positioned at or near the bottom side 270B of the containment frame 264. The one or more scavenge inlets 286 are in fluid communication with the injector/scavenge source 260 (illustrated in Figure 2B). With this design, the immersion fluid 248 that escapes in the frame gap 284 can be scavenged by the

injector/scavenge source 260. In the embodiment illustrated in Figure 2D, the bottom side 270B of the containment frame 264 includes one scavenge inlet 286 that is substantially annular groove shaped and is substantially concentric with the optical assembly 16. Alternatively, for example, the bottom side 270B of the
5 containment frame 264 can include a plurality of spaced apart annular groove shaped, scavenge inlets 286 that are substantially concentric with the optical assembly 16 to inhibit the immersion fluid 248 from completely exiting the frame gap 284. Still alternatively, a plurality of spaced apart apertures oriented in a circle can be used instead of an annular shaped groove.

10 In one embodiment, the injector/scavenge source 260 applies a vacuum and/or partial vacuum on the scavenge inlet 286. The partial vacuum draws the immersion fluid 248 between (i) a small land area 288 on the bottom side 270B, and (ii) the wafer 30 and/or the device stage 42. The immersion fluid 248 in the frame gap 284 acts as a fluid bearing 289A (illustrated as an arrow) that supports
15 the containment frame 264 above the wafer 30 and/or the device stage 42, allows for the containment frame 264 to float with minimal friction on the wafer 30 and/or the device stage 42, and allows for a relatively small frame gap 284. With this embodiment, most of the immersion fluid 248 is confined within the fluid barrier 254 and most of the leakage around the periphery is scavenged within the narrow
20 frame gap 284.

Additionally, the environmental system 26 can include a device for creating an additional fluid bearing 289B (illustrated as an arrow) between the containment frame 264 and the wafer 30 and/or the device stage 42. For example, the containment frame 264 can include one or more bearing outlets 290A that are in
25 fluid communication with a bearing fluid source 290B of a bearing fluid 290C (illustrated as triangles). In one embodiment, the bearing fluid 290C is air. In this embodiment, the bearing fluid source 290B provides pressurized air 290C to the bearing outlet 290A to create the aerostatic bearing 289B. The fluid bearings 289A, 289B can support all or a portion of the weight of the containment frame
30 264. In alternative embodiments, one or both of the fluid bearings 289A, 289B support approximately 1, 5, 10, 20, 30, 40, 50, 60, 70, 80, 90, or 100 percent of the weight of the containment frame 264. In one embodiment, the concentric fluid bearings 289A, 289B are used to maintain the frame gap 284.

Depending upon the design, the bearing fluid 290C can have the same composition or a different composition than the immersion fluid 248. However, some of the bearing fluid 290C may escape from the fluid barrier 254. In one embodiment, the type of bearing fluid 290C is be chosen so that the bearing fluid 290C and its vapor do not interfere with the measurement system 22 or temperature stability of the exposure apparatus 10.

In another embodiment, the partial vacuum in the scavenge inlets 286 pulls and urges the containment frame 264 towards the wafer 30. In this embodiment, the fluid bearing 289B supports part of the weight of the containment frame 264 as well as opposes the pre-load imposed by the partial vacuum in the scavenge inlets 286.

In addition, the pressurized air 290C helps to contain the immersion fluid 248 within the containment frame 264. As provided above, the immersion fluid 248 in the frame gap 284 is mostly drawn out through the scavenge inlets 286. In this embodiment, any immersion fluid 248 which leaks beyond the scavenge inlets 286 is pushed back to the scavenge inlets 286 by the bearing fluid 290C.

The frame gap 284 may vary radially, from the inner side 270C to the outer side 270D, to optimize bearing and scavenging functions.

In Figure 2D, the bearing outlet 290A is substantially annular groove shaped, is substantially concentric with the optical assembly 16 and the scavenge inlet 286, and has a diameter that is greater than the diameter of the scavenge inlet 286. Alternatively, for example, the bottom side 270B of the containment frame 264 can include a plurality of spaced apart annular groove shaped, bearing outlets 290A that are substantially concentric with the optical assembly 16. Still alternatively, a plurality of spaced apart apertures oriented in a circle can be used instead of an annular shaped groove. Alternatively, for example, a magnetic type bearing could be used to support the containment frame 264.

As illustrated in Figures 2B and 2D, the wafer 30 is centered under the optical assembly 16. In this position, the fluid bearings 289A, 289B support the containment frame 264 above the wafer 30. Figure 2E is an illustration of the portion of the exposure apparatus 10 of Figure 2A with the device stage 42 and the wafer 30 moved relative to the optical assembly 16. In this position, the wafer 30 and the device stage 42 are no longer centered under the optical assembly 16,

and the fluid bearings 289A, 289A (illustrated in Figure 2D) support the containment frame 264 above the wafer 30 and the device stage 42.

Figure 3 is a first embodiment of the injector/scavenge source 260. In this embodiment, the injector/scavenge source 260 includes (i) a low pressure source 392A, e.g. a pump, having an inlet that is at a vacuum or partial vacuum that is in fluid communication with the scavenge inlet 286 (illustrated in Figure 2D) and the pad inlets 278B (illustrated in Figures 2B and 2D) and a pump outlet that provides pressurized immersion fluid 248, (ii) a filter 392B in fluid communication with the pump outlet that filters the immersion fluid 248, (iii) an aerator 392C in fluid communication with the filter 392B that removes any air, contaminants, or gas from the immersion fluid 248, (iv) a temperature control 392D in fluid communication with the aerator 392C that controls the temperature of the immersion fluid 248, (v) a reservoir 392E in fluid communication with the temperature control 392D that retains the immersion fluid 248, and (vi) a flow controller 392F that has an inlet in fluid communication with the reservoir 392E and an outlet in fluid communication with the pad outlets 278A (illustrated in Figures 2B and 2D), the flow controller 392F controlling the pressure and flow to the pad outlets 278A. The operation of these components can be controlled by the control system 24 (illustrated in Figure 1) to control the flow rate of the immersion fluid 248 to the pad outlets 278A, the temperature of the immersion fluid 248 at the pad outlets 278A, the pressure of the immersion fluid 248 at the pad outlets 278A, and/or the pressure at the scavenge inlets 286 and the pad inlets 278B.

Additionally, the injector/scavenge source 260 can include (i) a pair of pressure sensors 392G that measure the pressure near the pad outlets 278A, the scavenge inlet 286 and the pad inlets 278B, (ii) a flow sensor 392H that measures the flow to the pad outlets 278A, and/or (iii) a temperature sensor 392I that measures the temperature of the immersion fluid 248 delivered to the pad outlets 278A. The information from these sensors 392G-392I can be transferred to the control system 24 so that that control system 24 can appropriately adjust the other components of the injector/scavenge source 260 to achieve the desired temperature, flow and/or pressure of the immersion fluid 248.

It should be noted that orientation of the components of the injector/scavenge source 260 can be varied. Further, one or more of the components may not be necessary and/or some of the components can be duplicated. For example, the injector/scavenge source 260 can include multiple pumps, multiple reservoirs, temperature controllers or other components. Moreover, the environmental system 26 can include multiple injector/scavenge sources 26.

The rate at which the immersion fluid 248 is pumped into and out of the chamber 263 (illustrated in Figure 2B) can be adjusted to suit the design requirements of the system. Further, the rate at which the immersion fluid 248 is scavenged from the pad inlets 278B and the scavenge inlets 286 can vary. In one embodiment, the immersion fluid 248 is scavenged from the pad inlets 278B at a first rate and is scavenged from the scavenge inlets 286 at a second rate. As an example, the first rate can be between approximately 0.1- 5 liters/minute and the second rate can be between approximately 0.01- 0.5 liters/minute. However, other first and second rates can be utilized.

It should be noted that the rates at which the immersion fluid 248 is pumped into and out of the chamber 263 can be adjusted to (i) control the leakage of the immersion fluid 248 below the fluid barrier, (ii) control the leakage of the immersion fluid 248 from the wafer gap 285 when the wafer 30 is off-center from the optical assembly 16, and/or (iii) control the temperature and purity of the immersion fluid 248 in the gap 246. For example, the rates can be increased in the event the wafer 30 is off-center, the temperature of the immersion fluid 248 becomes too high and/or there is an unacceptable percentage of contaminants in the immersion fluid 248 in the gap 246.

The type of immersion fluid 248 can be varied to suit the design requirements of the apparatus 10. In one embodiment, the immersion fluid 248 is water. Alternatively, for example, the immersion fluid 248 can be a fluorocarbon fluid, Fomblin oil, a hydrocarbon oil, or another type of oil. More generally, the fluid should satisfy certain conditions: 1) it must be relatively transparent to the exposure radiation; 2) its refractive index must be comparable to that of the last optical element 262B; 3) it should not react chemically with components of the exposure system 10 with which it comes into contact; 4) it must be homogeneous;

and 5) its viscosity should be low enough to avoid transmitting vibrations of a significant magnitude from the stage system to the last optical element 262B.

Figure 4A is an enlarged view of a portion of another embodiment of the fluid barrier 454A, a portion of the wafer 30, and a portion of the device stage 42.

5 In this embodiment, the fluid barrier 454A is somewhat similar to the corresponding component described above and illustrated in Figure 2D. However, in this embodiment, the containment frame 464A includes two concentric, scavenge inlets 486A that are positioned at the bottom side 470B of the containment frame 464A. The two scavenge inlets 486A are in fluid
10 communication with the injector/scavenge source 260 (illustrated in Figure 2B). With this design, the immersion fluid 248 that escapes in the frame gap 284 can be scavenged by the injector/scavenge source 260. In this embodiment, the bottom side 470B of the containment frame 464 includes two scavenge inlets 486A that are each substantially annular groove shaped and are substantially
15 concentric with the optical assembly 16.

With this design, the injector/scavenge source 260 applies a vacuum or partial vacuum on the scavenge inlets 486A. The partial vacuum draws the immersion fluid 248 between a small land area 488 on the bottom side 470B and the wafer 30 and/or the device stage 42. In this embodiment, the majority of the
20 immersion fluid 248 flows under the land 488 and into the inner scavenge inlet 486A. Additionally, the immersion fluid 248 not removed at the inner scavenge inlet 486A is drawn into the outer scavenge inlet 486A.

Figure 4B is an enlarged view of a portion of another embodiment of the fluid barrier 454B, a portion of the wafer 30, and a portion of the device stage 42.

25 In this embodiment, the fluid barrier 454B is somewhat similar to the corresponding component described above and illustrated in Figure 2D. However, in this embodiment, the containment frame 464B includes one bearing outlet 490B and two scavenge inlets 486B that are positioned at the bottom side 470B. The scavenge inlets 486B are in fluid communication with the
30 injector/scavenge source 260 (illustrated in Figure 2B) and the bearing outlet 490B is in fluid communication with the bearing fluid source 290C (illustrated in Figure 2D). However, in this embodiment, the bearing outlet 490B is positioned within and concentric with the scavenge inlets 486B. Stated another way, the bearing outlet 490B has a smaller diameter than the scavenge inlets 486B and the

bearing outlet 490B is closer to the optical assembly 16 than the scavenge inlets 486B. Further, with this design, the bearing fluid 290C (illustrated in Figure 2D) can be a liquid that is the same in composition as the immersion fluid 248. With this design, the bearing fluid 290C in the frame gap 284 can be scavenged by the injector/scavenge source 260 via the scavenge inlets 486B.

Figure 4C is an enlarged view of a portion of another embodiment of the fluid barrier 454C, a portion of the wafer 30, and a portion of the device stage 42. In this embodiment, the fluid barrier 454C is somewhat similar to the corresponding component described above and illustrated in Figure 2D. However, in this embodiment, the containment frame 464C includes one bearing outlet 490C and two scavenge inlets 486C that are positioned at the bottom side 470B. The scavenge inlets 486C are in fluid communication with the injector/scavenge source 260 (illustrated in Figure 2B) and the bearing outlet 490C is in fluid communication with the bearing fluid source 290C (illustrated in Figure 2D). However, in this embodiment, the bearing outlet 490C is positioned between the two scavenge inlets 486C. Stated another way, the inner scavenge inlet 486C has a smaller diameter than the bearing outlet 490C and the bearing outlet 490C has a smaller diameter than the outer scavenge inlet 486C. With this design, the inner scavenge inlet 486C is closer to the optical assembly 16 than the bearing outlet 490C.

It should be noted that in each embodiment, additional scavenge inlets and addition bearing outlets can be added as necessary.

Figure 5A is a cut-away view of a portion of another embodiment of the exposure apparatus 510, including the optical assembly 516, the device stage 542, and the environmental system 526 that are similar to the corresponding components described above. Figure 5A also illustrates the wafer 30, the gap 546, and that the immersion fluid 548 fills the gap 546. Figure 5B illustrates an enlarged portion of the Figure 5A taken on line 5B-5B.

However, in the embodiment illustrated in Figures 5A and 5B, the fluid barrier 554 includes an inner barrier 555 in addition to the containment frame 564, the seal 566, and the frame support 568. In this embodiment, the inner barrier 555 is annular ring shaped, encircles the bottom of the optical assembly 516, is concentric with the optical assembly 516, and is positioned within the containment frame 564 adjacent to the seal 566.

The inner barrier 555 can serve several purposes. For example, the inner barrier 555 can limit the amount of immersion fluid 548 escaping to the containment frame 564, reducing the scavenging requirements at the scavenge inlets 586, and also reducing the leakage of immersion fluid 548 into the wafer gap 285 when the wafer 30 is off-center from the optical assembly 516 and lying partly within and partly outside the fluid containment frame 564 region. With this design, the fluid injection/scavenge pads 558 can be used to recover the majority of the immersion fluid 548 from the chamber 563. Additionally, if the immersion fluid 548 is maintained at or near the level of the top of the inner barrier 555, pressure surges associated with injection of the immersion fluid 548 can be reduced, because excess immersion fluid 548 overflows the top of the inner barrier 555, creating a static pressure head. Some pressure surge may remain even in this situation due to surface tension effects. These effects can be reduced by increasing the distance W shown in Fig. 5B. For example, if the immersion fluid is water, W should preferably be several mm or more. Additionally, the remaining pressure surge can be reduced or eliminated by adjusting the "wettability" of the surfaces of inner barrier 555 and optical assembly 516 in contact with the immersion fluid 548 to reduce surface tension forces. In one embodiment, the inner barrier 555 can maintain a significant fluid height difference with a gap of approximately 50 μm between the bottom of the inner barrier 55 and the top of the wafer 30 or the device stage 42.

Figure 6 is a perspective view of one embodiment of a device stage 642 with a wafer 630 positioned above the device stage 642. In this embodiment, the device stage 642 includes a device table 650, a device holder 652, a guard 654, and a guard mover assembly 656. In this embodiment, the device table 650 is generally rectangular plate shaped. The device holder 652 retains the wafer 630. In this embodiment, the device holder 652 is a chuck or another type of clamp that is secured to the device table 650. The guard 654 surrounds and/or encircles the wafer 630. In one embodiment, the guard 654 is generally rectangular plate shaped and includes a circular shaped aperture 658 for receiving the wafer 630.

In one embodiment, the guard 654 can include a first section 660 and a second section 662. One or more of the sections 660, 662 can be moved,

removed or recessed to provide easy access for loading and removing the wafer 630.

5 The guard mover assembly 656 secures the guard 654 to the device table 650, and moves and positions the guard 654 relative to the device table 650, the device holder 652, and the wafer 630. With this design, the guard mover assembly 656 can move the guard 654 so that the top, stage surface 680 of the guard 654 is approximately at the same Z height as the top device exposed surface 679 of the wafer 630. Stated another way, the guard mover assembly 656 moves the guard 654 so that the device exposed surface 680 is approximately in
10 the same plane as the device exposed surface 679. As a result thereof, the guard 654 can be moved to adjust for wafers 630 of alternative heights.

The design of the guard mover assembly 656 can be varied. For example, the guard mover assembly 656 can include one or more rotary motors, voice coil motors, linear motors, electromagnetic actuators, and/or some other type of force
15 actuators. In one embodiment, the guard mover assembly 656 moves and positions the guard 654 along the Z axis, about the X axis and about the Y axis under the control of the control system 24 (illustrated in Figure 1). A sensor 681 (illustrated as a box) can be used to measure the relative heights of the guard surface 680 and the wafer top surface 679. Information from the sensor 681 can
20 be transferred to the control system 24 (illustrated in Figure 1) which uses information from the height sensor 681 to control the guard mover assembly 656.

Figure 7A is a perspective view of another embodiment of a device stage 742 with a wafer 730 positioned above the device stage 742. Figure 7B is a cut-away view taken from Figure 7A. In this embodiment, the device stage 742
25 includes a device table 750, a device holder 752, a guard 754, and a holder mover assembly 756. In this embodiment, the device table 750 is generally rectangular plate shaped. The device holder 752 retains the wafer 730. The guard 754 is generally rectangular plate shaped and includes a circular shaped aperture 758 for the wafer 730. In this embodiment, the guard 754 is fixedly secured to the
30 device table 750. The holder mover assembly 756 secures the device holder 752 to the device table 750 and moves and positions the device holder 752 relative to the device table 750 and the guard 754. With this design, the holder mover assembly 756 can move the device holder 752 and the wafer 730 so that the top stage surface 780 of the guard 754 is approximately at the same Z height as the

top device exposed surface 779 of the wafer 730. A sensor 781 can be used to measure the relative heights of the top stage surface 780 and the top device exposed surface 779. The information from the sensor 781 can be transferred to the control system 24 (illustrated in Figure 1) which uses information from the height sensor to control the holder mover assembly 756.

For example, the holder mover assembly 756 can include one or more rotary motors, voice coil motors, linear motors, electromagnetic actuators, and/or some other type of force actuators. In one embodiment, the holder mover assembly 756 moves and positions the device holder 750 and the wafer 730 along the Z axis, about the X axis and about the Y axis under the control of the control system 24 (illustrated in Figure 1).

Semiconductor devices can be fabricated using the above described systems, by the process shown generally in Figure 8A. In step 801 the device's function and performance characteristics are designed. Next, in step 802, a mask (reticle) having a pattern is designed according to the previous designing step, and in a parallel step 803 a wafer is made from a silicon material. The mask pattern designed in step 802 is exposed onto the wafer from step 803 in step 804 by a photolithography system described hereinabove in accordance with the present invention. In step 805 the semiconductor device is assembled (including the dicing process, bonding process and packaging process), finally, the device is then inspected in step 806.

Figure 8B illustrates a detailed flowchart example of the above-mentioned step 804 in the case of fabricating semiconductor devices. In Figure 8B, in step 811 (oxidation step), the wafer surface is oxidized. In step 812 (CVD step), an insulation film is formed on the wafer surface. In step 813 (electrode formation step), electrodes are formed on the wafer by vapor deposition. In step 814 (ion implantation step), ions are implanted in the wafer. The above mentioned steps 811 - 814 form the preprocessing steps for wafers during wafer processing, and selection is made at each step according to processing requirements.

At each stage of wafer processing, when the above-mentioned preprocessing steps have been completed, the following post-processing steps are implemented. During post-processing, first, in step 815 (photoresist formation step), photoresist is applied to a wafer. Next, in step 816 (exposure step), the above-mentioned exposure device is used to transfer the circuit pattern of a mask

(reticle) to a wafer. Then in step 817 (developing step), the exposed wafer is developed, and in step 818 (etching step), parts other than residual photoresist (exposed material surface) are removed by etching. In step 819 (photoresist removal step), unnecessary photoresist remaining after etching is removed.

5 Multiple circuit patterns are formed by repetition of these preprocessing and post-processing steps.

While the exposure apparatus 10 as shown and disclosed herein is fully capable of providing the advantages herein before stated, it is to be understood that it is merely illustrative of the presently preferred embodiments of the invention
10 and that no limitations are intended to the details of construction or design herein shown other than as described in the appended claims.

What is claimed is:

1. An environmental system for controlling an environment in a gap
2 between an optical assembly and a device, the device being retained by a device
stage, the environmental system comprising:
4 a fluid barrier that is positioned near the device; and
an immersion fluid system that delivers an immersion fluid that fills
6 the gap, and that collects immersion fluid that is directly between the fluid
barrier and at least one of the device and the device stage.
2. The environmental system of claim 1 wherein the fluid barrier
2 encircles the gap and inhibits the immersion fluid including fluid vapor from exiting
an area near the gap.
3. The environmental system of claim 1 wherein the fluid barrier
2 includes a scavenge inlet that is positioned near the device, and wherein the
immersion fluid system includes a low pressure source that is in fluid
4 communication with the scavenge inlet.
4. The environmental system of claim 3 further comprising a bearing
2 fluid source that directs a bearing fluid between the fluid barrier and at least one of
the device and the device table to support the fluid barrier relative to at least one
4 of the device and the device table.
5. The environmental system of claim 4 wherein the fluid barrier
2 includes a bearing outlet that is positioned near the device, the bearing outlet
being in fluid communication with the bearing fluid source, and wherein the
4 scavenge inlet is closer to the gap than the bearing outlet.
6. The environmental system of claim 4 wherein the fluid barrier
2 includes a bearing outlet that is positioned near to the device, the bearing outlet
being in fluid communication with the bearing fluid source, and wherein the
4 scavenge inlet is farther from the gap than the bearing outlet.

7. The environmental system of claim 1 further comprising a bearing
2 fluid source that directs a bearing fluid between the fluid barrier and at least one of
the device and the device table to support the fluid barrier relative to at least one
4 of the device and the device table.

8. The environmental system of claim 7 wherein the fluid barrier
2 includes a pair of spaced apart scavenge inlets and a bearing outlet that are
positioned near the device, wherein the immersion fluid system includes a low
4 pressure source that is in fluid communication with the scavenge inlets, and
wherein the bearing fluid source is in fluid communication with the bearing outlet.

9. The environmental system of claim 8 wherein the bearing outlet is
2 positioned between the scavenge inlets.

10. The environmental system of claim 7 wherein the pair of scavenge
2 inlets are positioned closer to the gap than the bearing outlet.

11. The environmental system of claim 1 further comprising a pressure
2 equalizer that allows the pressure in the gap to be approximately equal to the
pressure outside the fluid barrier.

12. The environmental system of claim 11 wherein the pressure
2 equalizer is a channel that extends through the fluid barrier.

13. An exposure apparatus for transferring an image to a device, the
2 exposure apparatus comprising: an optical assembly, a device stage that retains
the device, and the environmental system of claim 1 that controls an environment
4 in a gap between the optical assembly and the device.

14. The exposure apparatus of claim 13 wherein the device stage
2 includes a stage surface that is in approximately the same plane as a device
exposes a surface of the device.

15. A process for manufacturing a device that includes the steps of
2 providing a substrate and transferring an image to the substrate with the exposure
apparatus of claim 13.

16. An environmental system for controlling an environment in a gap
2 between an optical assembly and a device, the device being retained by a device
stage, the environmental system comprising:

4 a fluid barrier that is positioned near the device;
an immersion fluid system that delivers an immersion fluid that fills
6 the gap; and
a bearing fluid source that directs a bearing fluid between the fluid
8 barrier and at least one of the device and the device stage to support the
fluid barrier relative to at least one of the device and the device stage.

17. The environmental system of claim 16 wherein the fluid barrier
2 encircles the gap and inhibits the immersion fluid including any fluid vapor from
exiting an area near the gap.

18. The environmental system of claim 16 wherein the immersion fluid
2 system collects immersion fluid that is directly between the fluid barrier and at
least one of the device and the device stage.

19. The environmental system of claim 18 wherein the fluid barrier
2 includes a scavenge inlet that is positioned near the device, and wherein the
immersion fluid system includes a low pressure source that is in fluid
4 communication with the scavenge inlet.

20. The environmental system of claim 16 wherein the immersion fluid
2 has a different composition than the bearing fluid.

21. The environmental system of claim 16 wherein the immersion fluid
2 has approximately the same composition as the bearing fluid.

22. The environmental system of claim 16 wherein the fluid barrier
2 includes a bearing outlet that is positioned near the device, the bearing outlet
being in fluid communication with the bearing fluid source.

23. The environmental system of claim 16 further comprising a pressure
2 equalizer that allows the pressure in the gap to be approximately equal to the
pressure outside the fluid barrier.

24. The environmental system of claim 23 wherein the pressure
2 equalizer is a channel that extends through the fluid barrier.

25. An exposure apparatus for transferring an image to a device, the
2 exposure apparatus comprising: an optical assembly, a device stage that retains
the device, and the environmental system of claim 16 that controls an
4 environment in a gap between the optical assembly and the device.

26. The exposure apparatus of claim 25 wherein the device stage
2 includes a stage surface that is in approximately the same plane as a device
exposed surface of the device.

27. A process for manufacturing a device that includes the steps of
2 providing a substrate and transferring an image to the substrate with the exposure
apparatus of claim 25.

28. An exposure apparatus for transferring an image to a device, the
2 device including a device exposed surface, the exposure apparatus comprising:
an optical assembly positioned near the device with a gap between
4 the optical assembly and the device;
an environmental system that controls an environment in the gap,

6 the environmental system including a fluid barrier that is positioned near
the device, and an immersion fluid system that delivers an immersion fluid
8 that fills the gap; and
a device stage that retains the device, the device stage including a
10 stage surface that is in approximately the same plane as the device
exposed surface.

29. The exposure apparatus of claim 28 wherein the device stage
2 includes a device holder that retains the device, a guard that defines the stage
surface, and a mover assembly that moves one of the device holder and the
4 guard so that the device exposed surface is approximately in the same plane as
the stage surface.

30. The exposure apparatus of claim 29 wherein the mover assembly
2 moves the guard relative to the device and the device holder.

31. The exposure apparatus of claim 29 wherein the mover assembly
2 moves the device holder and the device relative to the guard.

32. The exposure apparatus of claim 29 wherein the guard includes a
2 first section that can be moved provide access to the device.

33. The exposure apparatus of claim 28 wherein the immersion fluid
2 system collects immersion fluid that is directly between the fluid barrier and at
least one of the device and the device stage.

34. The exposure apparatus of claim 28 further comprising a bearing
2 fluid source that directs a bearing fluid between the fluid barrier and at least one of
the device and the device table to support the fluid barrier relative to at least one
4 of the device and the device table.

35. The exposure apparatus of claim 28 further comprising a pressure
2 equalizer that allows the pressure in the gap to be approximately equal to the

pressure outside the fluid barrier.

36. A process for manufacturing a device that includes the steps of providing a substrate and transferring an image to the substrate with the exposure apparatus of claim 28.

37. A method for controlling an environment in a gap between an optical assembly and a device, the device being retained by a device stage, the method comprising the steps of:

positioning a fluid barrier near the device;

filling the gap with an immersion fluid using an immersion fluid system; and

collecting immersion fluid that is directly between the fluid barrier and at least one of the device and the device stage.

38. The method of claim 37 wherein the fluid barrier includes a scavenge inlet that is positioned near the device, and wherein the step of collecting immersion fluid includes the step of connecting a low pressure source to the scavenge inlet.

39. The method of claim 37 further comprising the step of directing a bearing fluid directly between the fluid barrier and at least one of the device and the device table with a bearing fluid source to support the fluid barrier relative to at least one of the device and the device table.

40. The method of claim 37 further comprising the step of making the pressure in the gap to be approximately equal to the pressure outside the fluid barrier with a pressure equalizer.

41. A method for making an exposure apparatus for transferring an image to a device, the method comprising the steps of providing an optical assembly, and controlling the environment in the gap by the method of claim 37.

42. A process for manufacturing a device that includes the steps of
2 providing a substrate and transferring an image to the substrate with the exposure
apparatus made by the method of claim 41.

43. A method for controlling an environment in a gap between an optical
2 assembly and a device, the device being retained by a device stage, the method
comprising the steps of:

4 positioning a fluid barrier near the device;

6 filling the gap with an immersion fluid using an immersion fluid
system; and

8 directing a bearing fluid directly between the fluid barrier and at least
one of the device and the device table with a bearing fluid source to
support the fluid barrier relative to at least one of the device and the device
10 stage.

44. The method of claim 43 further comprising the step of collecting
2 immersion fluid that is directly between the fluid barrier and at least one of the
device and the device stage.

45. The method of claim 44 wherein the fluid barrier includes a
2 scavenge inlet that is positioned near the device, and wherein the step of
collecting immersion fluid includes the step of connecting a low pressure source to
4 the scavenge inlet.

46. The method of claim 43 further comprising the step of making the
2 pressure in the gap to be approximately equal to the pressure outside the fluid
barrier with a pressure equalizer.

47. A method for making an exposure apparatus for transferring an
2 image to a device, the method comprising the steps of providing an optical
assembly, and controlling the environment in the gap by the method of claim 43.

48. A process for manufacturing a device that includes the steps of
2 providing a substrate and transferring an image to the substrate with the exposure
apparatus made by the method of claim 47.

49. A method for transferring an image to a device, the device including
2 a device exposed surface, the method comprising the steps of:

positioning an optical assembly near the device with a gap between
4 the optical assembly and the device;

controlling an environment in the gap with an environmental system,
6 the environmental system including a fluid barrier that is positioned near
the device, and an immersion fluid system that delivers an immersion fluid
8 that fills the gap; and

retaining the device with a device stage, the device stage including a
10 stage surface that is in approximately the same plane as the device
exposed surface.

50. The method of claim 49 wherein the device stage includes a device
2 holder that retains the device, a guard that defines the stage surface, and a mover
assembly that moves one of the device holder and the guard so that the stage
4 surface is approximately in the same plane as the device exposed surface.

51. The method of claim 50 wherein the mover assembly moves the
2 guard relative to the device and the device holder.

52. The method of claim 50 wherein the mover assembly moves the
2 device holder and the device relative to the guard.

53. The method of claim 50 further comprising the step of moving a first
2 section of the guard to provide access to the device.

54. A process for manufacturing a device that includes the steps of providing a substrate and transferring an image to the substrate with the exposure apparatus made by the method of claim 49.

55. An exposure apparatus for transferring an image to a work piece, the work piece including an exposed surface, the exposure apparatus comprising:
a stage that holds the work piece, the stage including a stage surface that is in approximately the same plane as the exposed surface of the work piece;
an optical assembly positioned with a gap between the optical assembly and at least one of the work piece and the stage;
an environmental system that controls an environment in the gap, the environmental system including a surrounding member which has a first surface facing at least one of the work piece and the stage, an immersion fluid system that delivers an immersion fluid within the surrounding member for filling the gap, and an inlet portion on the first surface of the surrounding member to inhibit the immersion fluid from leaking; and
wherein a distance between the first surface and at least one of the work piece and the stage is shorter than a distance between the end surface of the optical assembly and at least one of the work piece and the stage.

56. The exposure apparatus of claim 55 wherein the inlet portion is arranged to form a fluid bearing in the gap between the first surface and at least one of the work piece and the stage.

57. The exposure apparatus of claim 55 wherein the environmental system includes an outlet portion on the first surface of the surrounding member to inhibit immersion fluid from leaking.

58. The exposure apparatus of claim 57 wherein the outlet portion is arranged to provide pressurized gas.

59. The exposure apparatus of claim 58 wherein the outlet portion is
2 arranged to form a gaseous bearing in the gap between the first surface and at
least one of the work piece and the stage.

60. The exposure apparatus of claim 58 wherein the outlet portion is
2 disposed outside of the inlet portion relative to the gap adjacent the optical
assembly.

61. An exposure apparatus for transferring an image to a work piece,
2 the work piece including an exposed surface, the exposure apparatus comprising:
a stage that holds the work piece, the stage including a stage
4 surface that is in approximately the same plane as the exposed surface of
the work piece;
6 an optical assembly positioned with a gap between the optical
assembly and at least one of the work piece and the stage;
8 an environmental system that controls an environment in the gap,
the environmental system including a surrounding member which has a first
10 surface facing at least one of the work piece and the stage, an immersion
fluid system that delivers an immersion fluid within the surrounding member
12 for filling the gap, and an outlet portion on the first surface of the
surrounding member to inhibit the immersion fluid from leaking; and
14 wherein a distance between the first surface and at least one of the
work piece and the stage is shorter than a distance between the end
16 surface of the optical assembly and at least one of the work piece and the
stage.

62. The exposure apparatus of claim 61 wherein the outlet portion is
2 arranged to provide pressurized gas.

63. The exposure apparatus of claim 62 wherein the outlet portion is
2 arranged to form a gaseous bearing in the gap between the first surface and at
least one of the work piece and the stage.
